

Medallion architecture for data pipelines and machine learning

Medallion architecture used for data pipelines and ML (bronze/silver/gold) in the context of AI agents is explained below:

Medallion pattern (bronze/silver/gold) for AI agents

- *Purpose:* Organize data flows and model artifacts into progressive quality layers so agents can rely on increasingly refined inputs and outputs.
- **Bronze (raw):** Ingested, uncurated data (logs, sensor streams, agent interactions, prompts/responses). Used for debugging, reproducibility, and retraining raw models.
- **Silver (cleaned/enriched):** Deduplicated, normalized, labeled, and semantically enriched data (parsed intents, entity extraction, cleaned dialogues). Suitable for retrieval-augmented contexts and agent memory.
- **Gold (trusted/curated):** High-quality, validated datasets and canonical knowledge (human-reviewed dialogues, final knowledge graph nodes, curated tool outputs). Used for fine-tuning, evaluation, and high-stakes decision-making by agents.

How AI agents use each layer

- *Perception & ingestion:* Agents write to Bronze (raw observations, prompts, tool outputs).
- *Context building & memory:* Agents query Silver for searchable, indexed context and ephemeral memory.
- *Decision & execution:* Agents consult Gold for ground-truth facts, policies, and verified knowledge before critical actions.
- *Retraining & evaluation:* Bronze supports full audit trails; Silver accelerates retrieval and online learning; Gold is used for supervised fine-tuning and benchmarks.

Practical benefits

- Traceability and reproducibility.
- Faster retrieval with progressively smaller, higher-quality datasets.
- Safer, auditable decision-making for production agents.
- Clear separation between exploratory logs and production knowledge.
